Non-Solenoidal Startup via Helicity Injection in the Pegasus ST

M.W. BONGARD, G.M. BODNER, M.G. BURKE, R.J. FONCK, J.L. PACHICANO, J.M. PERRY, C. PIERREN, N.J. RICHNER, C. RODRIGUEZ SANCHEZ, D.J. SCHLOSSBERG, J.A. REUSCH, J.D. WEBERSKI, University of Wisconsin-Madison — Research on the $A \sim 1.2$ Pegasus ST is developing the physics and technology basis for optimal non-solenoidal tokamak startup. Recent work explores startup via Local Helicity Injection (LHI) using compact, multi-MW current sources placed at the plasma edge in the lower divertor region. This minimizes inductive drive from poloidal fields and dynamic shaping. Plasmas with $I_p \leq 200$ kA, $\Delta t_{\text{pulse}} \sim 20$ ms and $B_T \leq 0.15$ T are produced to date, sustained by two injectors with $A_{\text{inj}} = 4$ cm$^2$, $V_{\text{inj}} \sim 1.5$ kV, and $I_{\text{inj}} \sim 8$ kA, facilitated by improvements to the injectors, limiters, and divertor plates that mitigate deleterious PMI. These plasmas feature anomalous, reconnection-driven ion heating with $T_i \geq T_e \geq 50 - 100$ eV and large-amplitude MHD activity driven by the injectors. Under some conditions, MHD fluctuations abruptly decrease by over an order of magnitude without loss of LHI drive, improving realized $I_p$, and suggesting short-wavelength modes may relate to the current drive mechanism. The high $I_N \geq 10$, ion heating, and low $\ell_i$ driven by LHI, and the favorable stability of $A \sim 1$ STs allows access to record $\beta_l \sim 100\%$ and high $\beta_N \sim 6.5$. Such high-$\beta_l$ plasmas have a minimum $|B|$ well spanning $\sim 50\%$ of the plasma volume. Enhancements to the Pegasus facility are considered to increase $B_T$ towards NSTX-U levels; establish coaxial helicity injection capabilities; and add auxiliary heating and current drive.
